Question 1

Let $\psi(\lambda) = \frac{\lambda^2}{2}$. The Legendre-Fenchel transform of ψ is given by

$$\psi^*(\epsilon) = \sup_{\lambda \in \mathbb{R}} \lambda \epsilon - \psi(\lambda).$$

Subquestion 1.1

$$\psi^*(\epsilon) = \frac{\epsilon^2}{2}.$$

Solution

Let define $\psi_1(\lambda)$:

$$\psi_1(\lambda) = \lambda \epsilon - \frac{\lambda^2}{2}$$

Furthermore:

$$\psi_1'(\lambda) = \epsilon - \lambda$$

Since $\psi_1(\lambda)$ is a parabola it has only one extreme; particularly it has just a maximum (negative sign before λ^2). So, the maximum is reached at:

$$\lambda = \epsilon \quad \Rightarrow \quad \psi_1(\epsilon) = \epsilon \cdot \epsilon - \frac{\epsilon^2}{2} = \frac{\epsilon^2}{2}$$

We can conclude:

$$\psi^*(\epsilon) = \psi_1(\epsilon) = \frac{\epsilon^2}{2}$$

Subquestion 1.2

$$(\psi^*)^{-1}(z) = \pm \sqrt{2z}.$$

Solution

From previous point we know:

$$\psi^*(\epsilon) = \frac{\epsilon^2}{2}$$

It follows:

$$z = \frac{\epsilon^2}{2}$$
$$2z = \epsilon^2$$
$$\epsilon = \pm \sqrt{2z}$$

So:

$$(\psi^*)^{-1}(z) = \pm \sqrt{2z}$$

Question 2

The Blooper Reel

Subquestion 2.1

Deterministic fails for Adversarial Bandits Show that any deterministic algorithm (UCB included) has linear regret in the adversarial bandit setting. Hint: you can use the argument on the top of page 23.

Solution

We were a bit confused by this question, since it states that we need to find a linear regret, which we did not find. Instead we found that it can be bounded between two linear functions, but it does not necessarily is linear itself.

As a counter-example of the linearity we have that for n=0 no regret has been obtained. Therefore linearity only holds when $R_m + R_n = R_{n+m}$ for all n, m. But when we choose n=4, four arms and choose to play on arms 1,2,3 and 4 successively, we find $R_1=1$, $R_3=3$, $R_4=3$, so linearity dos not hold. It does however hold that it remains between our bounds $\frac{n}{K}$ and n for K the amount of arms.

We use the hint on the top of page 23, which tells us that for a deterministic forecaster, we can use the following sequence of losses:

$$\begin{aligned} &\text{if }I_t=1,\quad \text{then }l_{2,t}=0\quad \text{and}\quad l_{i,t}=1\quad \text{for all }i\neq 2;\\ &\text{if }I_t\neq 1,\quad \text{then }l_{1,t}=0\quad \text{and}\quad l_{i,t}=1\quad \text{for all }i\neq 1 \end{aligned}$$

This now implies the following for the regret:

$$R_n = \sum_{t=1}^{n} l_{t,I_t} - \min_k \sum_{t=1}^{n} l_n^k$$
$$= n - \min_k \sum_{t=1}^{n} l_n^k$$

But now for any choice of arm, with at least two arms, $\min_k \sum_{t=1}^n l_n^k$ is at most $\frac{n}{K}$. Therefore the regret is bounded from below by $\frac{n}{2}$ and since the loss function is nonnegative, the regret is also bounded from above by n. Thus it has a linear behaviour.

Question 3

We consider an adversarial bandit model with K^2 arms indexed by $i \in [K]$ and $j \in [K]$. For each arm (i,j), the loss at time t is $a_t^i + b_t^j$, where $a_t^i \in [0,1]$ and $b_t^j \in [0,1]$ are chosen by the adversary before the start of the interaction. Then each round the learner picks an arm $(I_t, J_t) \in [K]^2$ and observes $a_t^{I_t}$ and $b_t^{J_t}$ separately (and incurs their sum as the loss).

Subquestion 3.1

Consider running a single instance of EXP3 on all K^2 arms (with loss range [0,2]). Show that the expected pseudo-regret compared to the best arm (i^*,j^*) is bounded by

$$\bar{R}_n \le 2\sqrt{2nK^2\ln(K^2)}$$

Solution

Below we used the following facts:

- $\min x + y = \min x + \min y$; $x, y \ge 0$
- Linearity of expected value.
- Theorem from the lectures: $\bar{R}_n \leq \sqrt{2nK \ln K}$, where K is the number of arms; in our case we have K^2 arms.

$$\begin{split} \bar{R}_n &= \mathbb{E}_{I_1, \dots, I_n, J_1, \dots, J_n} \left\{ \sum_{t=1}^n a_t^{I_t} + b_t^{J_t} \right\} - \min_k \sum_{t=1}^n a_t^k + b_t^k \\ &= \left(\mathbb{E}_{I_1, \dots, I_n} \left\{ \sum_{t=1}^n a_t^{I_t} \right\} - \min_k \sum_{t=1}^n a_t^k \right) + \left(\mathbb{E}_{J_1, \dots, J_n} \left\{ \sum_{t=1}^n b_t^{J_t} \right\} - \min_k \sum_{t=1}^n b_t^k \right) \\ &\leq \sqrt{2nK^2 \ln K^2} + \sqrt{2nK^2 \ln K^2} \\ &= 2\sqrt{2nK^2 \ln K^2} \end{split}$$

Subquestion 3.2

Now we will use the a_t^i and b_t^j observations separately. Consider running two K-arm instances of EXP3, one with $i \to a_t^i$ as the loss and one with $j \to b_t^j$ as the loss. Have the first algorithm control I_t and the second J_t . Show that the overall expected pseudo-regret is bounded by

$$\bar{R}_n \le 2\sqrt{2nK\ln K}$$
.

Solution

We do similar as before, just that now we choose arm in the set of K arms and not K^2 .

$$\begin{split} \bar{R}_n &= \mathbb{E}_{I_1,...,I_n,J_1,...,J_n} \left\{ \sum_{t=1}^n a_t^{I_t} + b_t^{J_t} \right\} - \min_k \sum_{t=1}^n a_t^k + b_t^k \\ &= \left(\mathbb{E}_{I_1,...,I_n} \left\{ \sum_{t=1}^n a_t^{I_t} \right\} - \min_k \sum_{t=1}^n a_t^k \right) + \left(\mathbb{E}_{J_1,...,J_n} \left\{ \sum_{t=1}^n b_t^{J_t} \right\} - \min_k \sum_{t=1}^n b_t^k \right) \\ &\leq \sqrt{2nK \ln K} + \sqrt{2nK \ln K} \\ &= 2\sqrt{2nK \ln K} \end{split}$$
